Comparison of 256-bit stream ciphers at the beginning of 2006

Daniel J. Bernstein *

djb@cr.yp.to

Abstract. This paper evaluates and compares several stream ciphers that use 256-bit keys: counter-mode AES, CryptMT, DICING, Dragon, FUBUKI, HC-256, Phelix, Py, Py6, Salsa20, SOSEMANUK, VEST, and YAMB.

1 Introduction

ECRYPT, a consortium of European research organizations, issued a Call for Stream Cipher Primitives in November 2004. A remarkable variety of ciphers were proposed in response by a total of 97 authors spread among Australia, Belgium, Canada, China, Denmark, England, France, Germany, Greece, Israel, Japan, Korea, Macedonia, Norway, Russia, Singapore, Sweden, Switzerland, and the United States.

Evaluating a huge pool of stream ciphers, to understand the merits of each cipher, is not an easy task. This paper simplifies the task by focusing on the relatively small pool of ciphers that allow 256-bit keys. Ciphers limited to 128-bit keys (or 80-bit keys) are ignored. See Section 2 to understand my interest in 256-bit keys.

The ciphers allowing 256-bit keys are CryptMT, DICING, Dragon, FUBUKI, HC-256, Phelix, Py, Py6, Salsa20, SOSEMANUK, VEST, and YAMB. I included 256-bit AES in counter mode as a basis for comparison. Beware that there are unresolved claims of attacks against Py (see [4] and [3]), SOSEMANUK (see [1]), and YAMB (see [5]).

ECRYPT, using measurement tools written by Christophe De Cannière, has published timings for each cipher on several common general-purpose CPUs. The original tools and timings used reference implementations (from the cipher authors) but were subsequently updated for faster implementations (also from the cipher authors). I extended the list of CPUs and then wrote a few extra tools, now available from http://cr.yp.to/streamciphers.html#timings, to convert ECRYPT's timings into the tables and graphs shown in Section 3.

Section 4 discusses several other interesting cipher features. For example, some ciphers have "free" built-in message authentication, so users can avoid the cost of computing a separate authenticator. One can and should quantify this benefit by making a separate table of timings for authenticated encryption; I plan to do this in subsequent comparison papers.

2 Why use 256-bit keys?

Some readers may wonder why I am not satisfied with 128-bit keys. Haven't I heard that—without massive advances in computer technology—a brute-force attack will never find a 128-bit key? After all, if checking about 2²⁰ keys per second requires a CPU costing about 2⁶ dollars, then searching 2¹²⁸ keys in a year will cost an inconceivable 2⁸⁹ dollars.

Answer: Even without advances in computer technology, the attacker does not need to spend 2^{89} dollars. Here are three reasons that lower-cost attacks are a threat:

- The attacker can succeed in far fewer than 2^{128} computations. He reaches success probability p after just $2^{128}p$ computations.
- More importantly, each key-checking circuit costs far less than 2^6 dollars, at least in bulk: 2^{10} or more key-checking circuits can fit into a single chip, effectively reducing the attacker's costs by a factor of 2^{10} .
- Even more importantly, if the attacker simultaneously attacks (say) 2^{40} keys, he can effectively reduce his costs by a factor of 2^{40} .

One can counter the third reduction by putting extra randomness into nonces, but putting the same extra randomness into keys is less expensive.

See [2] for a much more detailed discussion of these issues.

3 Speed

Ciphers in the tables in this section are sorted by a low-level feature, namely the number of bytes of state recorded between blocks. At one extreme is HC-256, which expands a key and nonce into a pair of 4096-byte arrays, making several array modifications for each block. At the other extreme is Salsa20, which simply records a key, nonce, and block counter in a 64-byte array, performing computations anew for each block. Most ciphers lie somewhere in the middle.

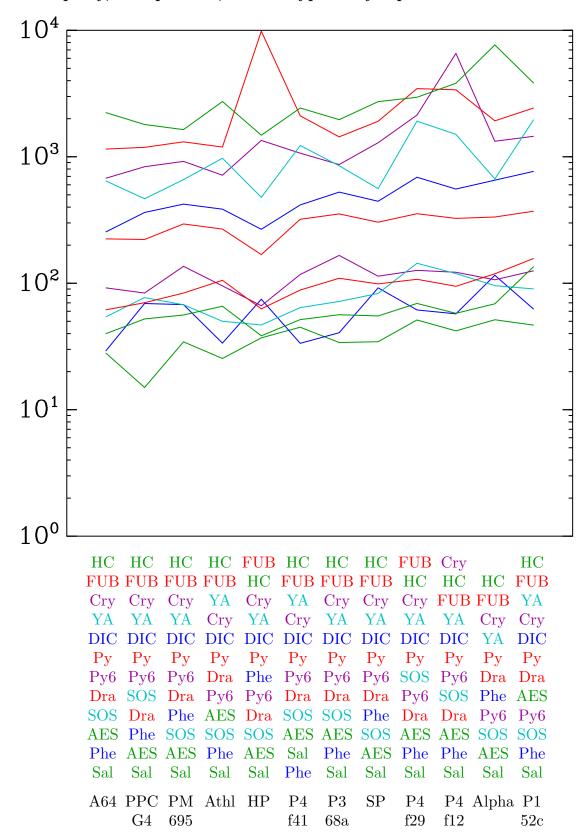

This ordering is not meant to imply that one extreme is better than the other. A large state has both advantages and disadvantages: it is expensive to set up and maintain, but it is also expensive for the attacker to analyze.

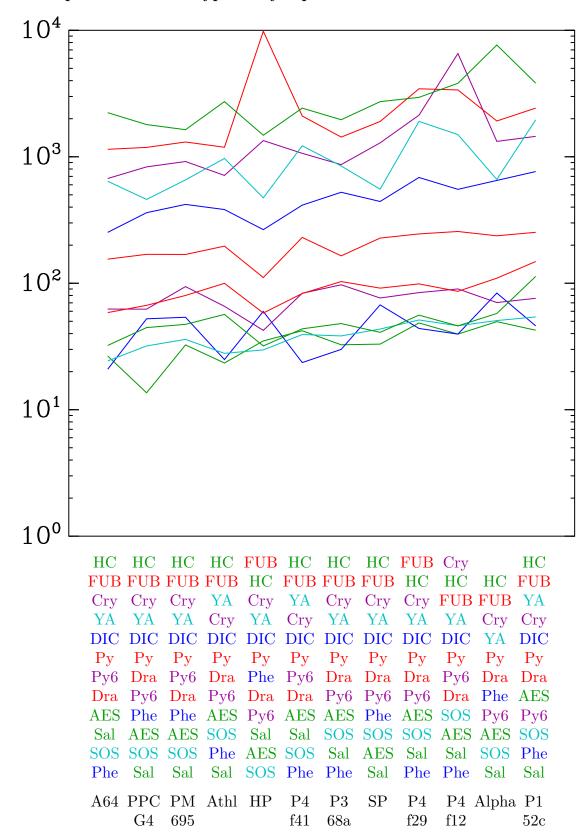

Table entries measure times for key setup, nonce setup, and encryption. All times are expressed as the number of cycles per encrypted byte. Smaller numbers are better here. Lines vary in how much setup they include, how many bytes are encrypted, and which CPU is measured. Bonus for readers using color displays: red means slower than AES; blue means faster than AES; lighter blue means twice as fast as AES; green means three times faster than AES.

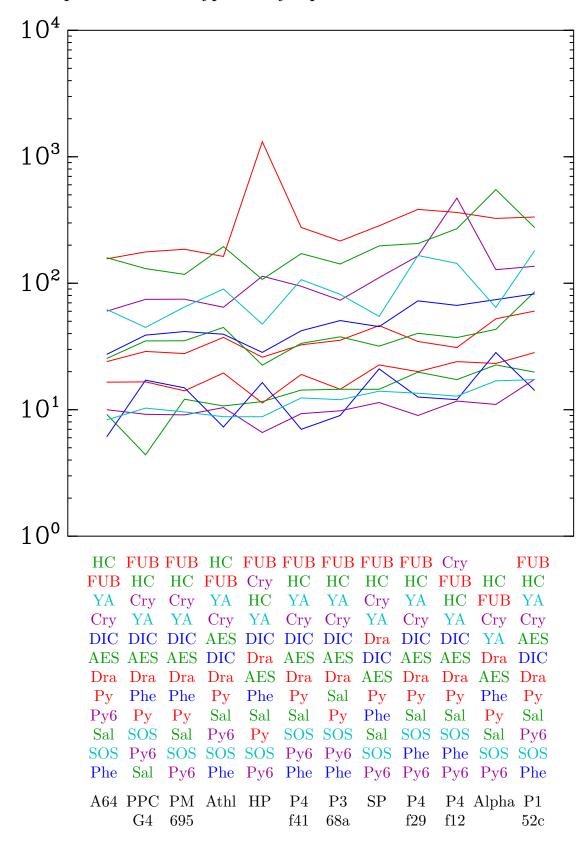

FUBUKI has been omitted from the tables in this section. VEST has been omitted from the tables and graphs in this section. The cycle counts for FUBUKI and VEST are too large to be interesting.

Notes on the timings

The tables and graphs use the following representative set of 12 machines, all with version 156 (2006.01.16) of ECRYPT's timing suite except where otherwise noted:

- A64: 2000MHz (one of two CPU cores) AMD Athlon 64 X2 (CPU identifier 15/43/1) named cph (gcc 4.0.2, Ubuntu 5.10).
- PPC G4: 533MHz (one of two CPUs) Motorola PowerPC G4 7410 named gggg (gcc 4.0.2, Ubuntu 5.10).
- PM 695: 1300MHz Intel Pentium M (695) named whisper (Fedora).
- Athlon: 900MHz AMD Athlon (622) named that (gcc 4.0.2, Ubuntu 5.10).
- HP PA: 440MHz (one of two CPUs) HP 9000/785 J5000 named hp400 (HP/UX).
- P4 f41: 3000MHz Intel Pentium 4 (f41) named pentium4b, timings collected by Christophe De Cannière.
- P3 68a: 1000MHz (one of two CPUs) Intel Pentium III (68a) named neumann (gcc 2.95.4 and gcc 3.0.4, Debian).
- SPARC: 900MHz Sun UltraSPARC III named wessel (SunOS 5.9).
- P4 f29: 2800MHz (one of two CPUs) Intel Pentium 4 (f29) named rzitsc (gcc 3.2.3, Red Hat).
- P4 f12: 1900MHz Intel Pentium 4 (f12) named fireball (gcc 4.0.2, Ubuntu 5.10).
- Alpha: 400MHz DEC Alpha EV5.6 21164A named alpha, using version 140 (2005.12.21), timings collected by Christophe De Cannière.
- P1 52c: 133MHz Intel Pentium (52c) named cruncher (gcc 4.0.2, Ubuntu 5.10).

The machines are sorted by the geometric average of all cipher cycle counts. This sorting accounts for the overall left-to-right upward trend in the graphs on previous pages.

See my web page http://cr.yp.to/streamciphers.html#timings for more comprehensive data. The web page includes speed reports for 24 machines; I'd also like to include timings for 8-bit CPUs and for ASICs. I will continue to update the web page as I receive newer information.

The graphs use cycles per byte, with a logarithmic scale, for the vertical axis. The labels below the graphs list ciphers in speed order. Consider, for example, the first graph: "Set up key, set up nonce, and encrypt 40-byte packet." The first column of the graph is labelled, from top to bottom, HC FUB Cry YA DIC Py Py6 Dra SOS AES Phe Sal A64. This column shows that, for setup and 40-byte encryption on an Athlon 64 (A64), HC-256 (HC) takes the most cycles per byte, and Salsa20 (Sal) takes the fewest cycles per byte. The graph shows that HC-256 takes about $2 \cdot 10^3$ cycles per byte while Salsa20 takes about $3 \cdot 10^1$ cycles per byte. The earlier table shows that HC-256 takes 2236.5 cycles per byte (i.e., 89460 cycles for 40 bytes) while Salsa20 takes 28.1 cycles per byte (i.e., 1124 cycles for 40 bytes).

4 Additional features

Bonus for readers using color displays: in this section, blue means an advantage compared to AES, and red means a disadvantage compared to AES.

AES in counter mode

Encryption. Unpatented. Variable time. 256-bit security conjecture. Security margin: has faster reduced-round versions; Ferguson et al. reported an attack on 7 out of 14 rounds; as far as I know, all claimed attacks on 8 rounds actually have worse price-performance ratio than brute-force search; there are no public claims of attacks on 9 rounds.

CryptMT

Encryption. Patented. Constant time. 256-bit security conjecture. No explicit security margin.

DICING

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin.

Dragon

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin.

FUBUKI

Encryption. Patented. Variable time. 256-bit security conjecture. No explicit security margin.

HC-256

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin.

Phelix

Authenticated encryption. Unpatented. Constant time. 128-bit security conjecture. No explicit security margin.

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin. Attacks: Sekar, Paul, and Preneel in [4] reported an attack on Py using 2⁸⁸ output bytes and comparable time. Crowley in [3] reduced 2⁸⁸ to 2⁷². The authors have not yet responded.

Py6

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin. Attacks: The attacks on Py by Sekar et al. can, presumably, be extended to Py6.

Salsa20

Encryption. Unpatented. Constant time. 256-bit security conjecture. Security margin: has faster reduced-round versions; Crowley reported an attack on 5 out of 20 rounds; there are no public claims of attacks on 6 rounds.

SOSEMANUK

Encryption. Unpatented. Variable time. 128-bit security conjecture. No explicit security margin. Attacks: Ahmadi, Eghlidos, and Khazaei in [1] reported an attack on SOSEMANUK using 2²²⁶ simple operations—but this doesn't disprove the original 128-bit security conjecture for SOSEMANUK. The authors have not yet responded.

VEST

Authenticated encryption. Patented. Variable time. 256-bit security conjecture. No explicit security margin.

YAMB

Encryption. Unpatented. Variable time. 256-bit security conjecture. No explicit security margin. Attacks: Wu and Preneel in [5] reported an attack on YAMB requiring 2^{58} output blocks and comparable time. There has been no response from the authors after six months.

5 Recommendations

Py, Py6, SOSEMANUK, and YAMB don't appear to provide 256-bit security. Unless there's a dispute regarding the attacks on these ciphers, they should be eliminated from consideration, at least as competition for 256-bit AES.

FUBUKI has no apparent advantages over AES and is several times slower. Unless there are dramatic speedups in the FUBUKI software, FUBUKI should be eliminated from consideration.

VEST is painfully slow in software but is claimed to provide considerably better performance in hardware. I haven't seen a careful evaluation of hardware performance, so I won't make any recommendations now regarding VEST.

The remaining 256-bit stream ciphers are CryptMT, DICING, Dragon, HC-256, Phelix, and Salsa20. Each of these ciphers provides better performance than AES for long streams, and some of them provide better performance than AES in other situations.

I recommend keeping all six ciphers—CryptMT, DICING, Dragon, HC-256, Phelix, and Salsa20—under consideration. One might be tempted to say, e.g., "CryptMT is practically always slower than Phelix and should be eliminated," but this will sound quite silly in retrospect if Phelix turns out to be breakable. The initial stream-cipher submission deadline was only eight months ago; the Py and SOSEMANUK attacks were published only a month ago; obviously we need more time for cryptanalysis.
